

# Database Programming with PL/SQL

## 8-3: Passing Parameters

## **Practice Activities**

### Vocabulary

Identify the vocabulary word for each definition below:

OUT PARAMETER	Returns a value to the caller
IN PARAMETER	Provides values for a subprogram to process
NAMED NOTATION	Lists the actual parameters in arbitrary order and uses the association operator ( '=>' which is an equal and an arrow together) to associate a named formal parameter with its actual parameter
COMBINATION NOTATION	Lists some of the actual parameters as positional (no special operator) and some as named (with the => operator)
POSITIONAL NOTATION	Lists the actual parameters in the same order as the formal parameters
IN OUT PARAMETER	Supplies an input value, which may be returned as a modified value

#### Try It / Solve It

1. Name the three modes for parameters and indicate which mode is the default mode. Which mode cannot be modified inside the procedure?

Posición, nombre y combinado, el que es por posición es por defecto

#### 2. Procedures:

A. Create a procedure that receives a country\_id as an IN parameter and returns the name and population of that country as OUT parameters. Include an exception handler to trap the NO\_DATA\_FOUND exception if the country does not exist. The procedure should not display the returned values; this will be done in the next step. Name your procedure find\_area\_pop. Save your code.

CREATE OR REPLACE PROCEDURE find\_area\_pop(

p\_id IN countries.country\_id%type,

v\_name OUT countries.country\_name%type,

v\_population OUT countries.population%type)

AS

**BEGIN** 

SELECT country\_name, population INTO v\_name, v\_population FROM COUNTRIES WHERE country\_id=p\_id;

END;

B. Test your procedure by creating and executing an anonymous block which invokes the procedure and displays the returned OUT values. Save your code. Run the block twice, with country\_ids 2 (Canada) and 10 (does not exist).

#### **DECLARE**

```
v_name countries.country_name%type;
v_population countries.population%type;
v_id countries.country_id%type:=2;
BEGIN
find_area_pop(v_id, v_name, v_population);
dbms_output.put_line(v_name || ' '|| v_population);
END;
```

C. Retrieve your procedure code and modify it to add a third OUT parameter which is the population density of the country, using the formula: density = (population / area). You will need to modify your SELECT statement to fetch the area column value into a local variable. Save your modified code.

```
CREATE OR REPLACE PROCEDURE find_area_pop(
p_id IN countries.country_id%type,
v_name OUT countries.country_name%type,
v_population OUT countries.population%type,
V_densidad OUT NUMBER)
AS
```

```
v_area countries.area%type;
```

#### **BEGIN**

SELECT country\_name, population, area INTO v\_name, v\_population, v\_area FROM COUNTRIES WHERE country\_id=p\_id;

```
v_densidad:= (v_population/v_area);
```

#### END;

D. Test your modifed procedure using country\_id 2. You will need to modify your calling anonymous block to declare and pass a fourth actual parameter to receive the population density from the procedure. Save your code.

#### **DECLARE**

```
v_name countries.country_name%type;
```

v\_population countries.population%type;

v\_id countries.country\_id%type:=2;

v\_densidad NUMBER(5,2);

#### **BEGIN**

END;

```
find_area_pop(v_id, v_name, v_population,v_densidad);
dbms_output.put_line(v_name || ' '|| v_population || ' '||v_densidad );
```

3. Create a procedure which accepts an integer as an IN OUT parameter and returns the square of that integer, for example the square of 4 is 16. Save your code. Test your procedure from an anonymous block three times, using integer values 4, 7, and –20 (negative 20).

```
CREATE OR REPLACE PROCEDURE square(
p_var IN OUT NUMBER
) AS

begin
p_var:= p_var*p_var;
end;

DECLARE
var NUMBER:=6;
begin
square(var);
DBMS_OUTPUT.PUT_LINE(var);
END;
```

4. List the three methods of passing parameters to a procedure.

IN, OUT, IN OUT.

A. Retrieve your anonymous block from question 2D and modify its call to find\_area\_pop to pass the four parameters using named notation. Test your block, again using country\_id 2 (Canada).

If you have forgotten the p\_ names of the procedure's formal parameters, how can you refresh your memory?

```
DESC find_area_pop;
```

B. Modify the anonymous block from the previous step to pass the FIRST two parameters using named notation and the LAST two using positional notation. Test the block again. What happens?

No funciona, porque al usar los parámetros por nombre se pierde la posicion

C. Correct the problem in the previous step by modifying the anonymous block again to pass the first two parameters using positional notation and the last two using named notation. Test the block again.

#### **DECLARE**

v\_name countries.country\_name%type;

```
v_population countries.population%type;
v_id countries.country_id%type:=2;
v_densidad NUMBER(5,2);
BEGIN
find_area_pop(v_id, v_name,v_population=>v_population, v_densidad=>v_densidad);
dbms_output.put_line(v_name || ' '|| v_population || ' '|| v_densidad );
END;
```

5. In your own words, describe the purpose of the DEFAULT option for parameters and state the two syntax options for providing the default value in the procedure header.

Los parametros son variables que recibe un procedimiento, son útiles porque se evita tener repetir código para adaptarlo a cada caso.

Existen dos formas de asignar un valor por defecto a un parámetro

P\_var NUMBER := 10;

P\_var NUMBER :=DEFAULT 1400;

6. Find the country\_id of your own country by executing a suitable SELECT...FROM countries.... Then retrieve your find\_area\_pop procedure from question 2C. Modify the code to use your country\_id as a default value for the country\_id IN parameter. Save your code. Then retrieve your anonymous block from question 2D and modify it so that it does NOT pass the country\_id to the procedure. Test the block and check that your country's details are returned and displayed. If your modified anonymous block does not work, correct it so it will.

```
CREATE OR REPLACE PROCEDURE find_area_pop(
```

p\_id IN out countries.country\_id%type DEFAULT 52,

v name OUT countries.country name%type,

v population OUT countries.population%type,

V\_densidad OUT NUMBER)

AS

v\_area countries.area%type;

**BEGIN** 

SELECT country\_name, population, area INTO v\_name, v\_population, v\_area FROM COUNTRIES WHERE country\_id=p\_id;

v\_densidad:= (v\_population/v\_area);

END;

#### **DECLARE**

```
v_name countries.country_name%type;
v_population countries.population%type;
v_id countries.country_id%type:=2;
v_densidad NUMBER(5,2);
BEGIN
find_area_pop(v_name=>v_name,
v_population=>v_population,v_densidad=>v_densidad);
dbms_output.put_line(v_name || ' '|| v_population || ' '||v_densidad );
END;
```
